Algorithms

ROBERT SEDGEWICK | KEVIN WAYNE

Substring search
Goal. Find pattern of length M in a text of length N.

typically N >> M

pattern ⟶ N E E D L E

text ⟶ I N A H A Y S T A C K N E E D L E I N A

match

Substring search applications

Goal. Find pattern of length M in a text of length N.

typically N >> M

pattern $\longrightarrow$ N E E D L E

text $\longrightarrow$ I N A H A Y S T A C K N E E D L E I N A

match

Substring search applications

Goal. Find pattern of length M in a text of length N.

typically N >> M

pattern ⟶ N E E D L E

text ⟶ I N A H A Y S T A C K N E E D L E I N A

match

Computer forensics. Search memory or disk for signatures, e.g., all URLs or RSA keys that the user has entered.

http://citp.princeton.edu/memory

Substring search applications

Goal. Find pattern of length M in a text of length N.

typically N >> M

pattern ⟶ N E E D L E

text ⟶ I N A H A Y S T A C K N E E D L E I N A

Substring search applications

Screen scraping. Extract relevant data from web page.

Ex. Find string delimited by `<b>` and `</b>` after first occurrence of pattern `Last Trade:`.

http://finance.yahoo.com/q?s=goog

```
...
<tr>
<td class= "yfnc_tablehead1"
width= "48%">
Last Trade:
</td>
<td class= "yfnc_tabledata1">
<big><b>452.92</b></big>
</td></tr>
<td class= "yfnc_tablehead1"
width= "48%">
Trade Time:
</td>
<td class= "yfnc_tabledata1">
...
```

Screen scraping: Java implementation

Java library. The `indexOf()` method in Java's string library returns the index of the first occurrence of a given string, starting at a given offset.

```java
public class StockQuote
{
    public static void main(String[] args)
    {
        String name = "http://finance.yahoo.com/q?s=";
        In in = new In(name + args[0]);
        String text = in.readAll();
        int start    = text.indexOf("Last Trade:", 0);
        int from     = text.indexOf("<b>",  start);
        int to       = text.indexOf("</b>", from);
        String price = text.substring(from + 3, to);
        StdOut.println(price);
    }
}
```

```
% java StockQuote goog
582.93

% java StockQuote msft
24.84
```

5.3 Substring Search

Algorithms

Robert Sedgewick | Kevin Wayne

http://algs4.cs.princeton.edu

Brute-force substring search

Check for pattern starting at each text position.

i	j	i+j	0	1	2	3	4	5	6	7	8	9	10
		txt →	A	B	A	C	A	D	A	B	R	A	C
0	2	2	A	B	R	A ← pat							
1	0	1		A	B	R	A						
2	1	3			A	B	R	A					
3	0	3				A	B	R	A				
4	1	5					A	B	R	A			
5	0	5						A	B	R	A		
6	4	10							A	B	R	A	

entries in red are mismatches

entries in gray are for reference only

entries in black match the text

6 *return i when j is M*

match

Brute-force substring search: Java implementation

Check for pattern starting at each text position.

i	j	i + j	0	1	2	3	4	5	6	7	8	9	10
			A	B	A	C	A	D	A	B	R	A	C
4	3	7					A	D	A	C	R		
5	0	5						A	D	A	C	R	

```
public static int search(String pat, String txt)
{
    int M = pat.length();
    int N = txt.length();
    for (int i = 0; i <= N - M; i++)
    {
        int j;
        for (j = 0; j < M; j++)
            if (txt.charAt(i+j) != pat.charAt(j))
                break;
        if (j == M) return i;      ←  index in text where
    }                                  pattern starts
    return N;    ←  not found
}
```

Brute-force substring search: worst case

Brute-force algorithm can be slow if text and pattern are repetitive.

| i	j	i+j	0	1	2	3	4	5	6	7	8	9
		txt $\longrightarrow$	A	A	A	A	A	A	A	A	A	B
0	4	4	A	A	A	A	B $\longleftarrow$ pat					
1	4	5		A	A	A	A	B				
2	4	6			A	A	A	A	B			
3	4	7				A	A	A	A	B		
4	4	8					A	A	A	A	B	
5	5	10						A	A	A	A	B

match

Worst case. $\sim M\,N$ char compares.

Backup

In many applications, we want to avoid backup in text stream.

- Treat input as stream of data.
- Abstract model: standard input.

"ATTACK AT DAWN"
substring search
machine

found ○

Brute-force algorithm needs backup for every mismatch.

matched chars   mismatch

A A A A A A A A A A A A A A A A A A A A A B

A A A A A B

backup

A A A A A A A A A A A A A A A A A A A A A A B

A A A A A B

shift pattern right one position

Approach 1. Maintain buffer of last M characters.

Approach 2. Stay tuned.

Brute-force substring search: alternate implementation

Same sequence of char compares as previous implementation.

- `i` points to end of sequence of already-matched chars in text.
- `j` stores # of already-matched chars (end of sequence in pattern).

```
 i   j    0  1  2  3  4  5  6  7  8  9  10
          A  B  A  C  A  D  A  B  R  A  C
 7   3                A  D  A  C  R
 5   0                   A  D  A  C  R
```

```
public static int search(String pat, String txt)
{
   int i, N = txt.length();
   int j, M = pat.length();
   for (i = 0, j = 0; i < N && j < M; i++)
   {
      if (txt.charAt(i) == pat.charAt(j)) j++;
      else { i -= j; j = 0;  }
   }
   if (j == M) return i - M;
   else               return N;
}
```

explicit backup

Algorithmic challenges in substring search

Brute-force is not always good enough.

Theoretical challenge. Linear-time guarantee. ← fundamental algorithmic problem

Practical challenge. Avoid backup in text stream. ← often no room or time to save text

```

5.3 SUBSTRING SEARCH

- ▸ *introduction*
- ▸ *brute force*
- ▸ **Knuth-Morris-Pratt**
- ▸ *Boyer-Moore*
- ▸ *Rabin-Karp*

Knuth-Morris-Pratt substring search

Intuition.   Suppose we are searching in text for pattern BAAAAAAAA.
- Suppose we match 5 chars in pattern, with mismatch on 6^{th} char.
- We know previous 6 chars in text are BAAAAB.
- Don't need to back up text pointer!

assuming { A, B } alphabet

i
↓

text

A B A A A A B A A A A A A A A A

after mismatch
on sixth char → B A A A A A A A A A ← pattern

brute-force backs
up to try this → B A A A A A A A A A

B A A A A A A A A A

and this → B A A A A A A A A A

and this → B A A A A A A A A A

and this → B A A A A A A A A A

but no backup
is needed → B A A A A A A A A A

Knuth-Morris-Pratt algorithm.   Clever method to always avoid backup. (!)

Deterministic finite state automaton (DFA)

DFA is abstract string-searching machine.

- Finite number of states (including start and halt).
- Exactly one transition for each char in alphabet.
- Accept if sequence of transitions leads to halt state.

internal representation

j	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
A	1	1	3	1	5	1
dfa[][j] B	0	2	0	4	0	4
C	0	0	0	0	0	6

If in state j reading char c:
  if j is 6 halt and accept
  else move to state dfa[c][j]

graphical representation
A A B A C A A B A B A C A A

		0	1	2	3	4	5
pat.charAt(j)		A	B	A	B	A	C
	A	1	1	3	1	5	1
dfa[][j]	B	0	2	0	4	0	4
	C	0	0	0	0	0	6

A A B A C A **A B A B A C** A A

↑

	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
A	1	1	3	1	5	1
dfa[][j] B	0	2	0	4	0	4
C	0	0	0	0	0	6

substring found
Interpretation of Knuth-Morris-Pratt DFA

Q. What is interpretation of DFA state after reading in `txt[i]`?

A. State = number of characters in pattern that have been matched.

length of longest prefix of `pat[]` that is a suffix of `txt[0..i]`

Ex. DFA is in state 3 after reading in `txt[0..6]`.
```
                            i
        0  1  2  3  4  5  6  7  8              0  1  2  3  4  5
txt ⟶   B  C  B  A  A  B  A  C  A     pat ⟶   A  B  A  B  A  C
            suffix of txt[0..6]                  prefix of pat[]
```
Knuth-Morris-Pratt substring search: Java implementation

Key differences from brute-force implementation.

- Need to precompute `dfa[][]` from pattern.
- Text pointer `i` never decrements.

```java
public int search(String txt)
{
    int i, j, N = txt.length();
    for (i = 0, j = 0; i < N && j < M; i++)
        j = dfa[txt.charAt(i)][j];                    ← no backup
    if (j == M) return i - M;
    else        return N;
}
```

Running time.

- Simulate DFA on text: at most N character accesses.
- Build DFA: how to do efficiently? [warning: tricky algorithm ahead]

Knuth-Morris-Pratt substring search: Java implementation

Key differences from brute-force implementation.

- Need to precompute `dfa[][]` from pattern.
- Text pointer `i` never decrements.
- Could use input stream.

```java
public int search(In in)
{
    int i, j;
    for (i = 0, j = 0; !in.isEmpty() && j < M; i++)
        j = dfa[in.readChar()][j];
    if (j == M) return i - M;
    else        return NOT_FOUND;
}
```

no backup

Include one state for each character in pattern (plus accept state).

	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
A	1	1	3	1	5	1
dfa[][j] B	0	2	0	4	0	4
C	0	0	0	0	0	6

Constructing the DFA for KMP substring search for A B A B A C
How to build DFA from pattern?

Include one state for each character in pattern (plus accept state).

	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
dfa[][j] A						
B						
C						

⓪   ①   ②   ③   ④   ⑤   ⑥

How to build DFA from pattern?

Match transition. If in state `j` and next char `c == pat.charAt(j)`, go to `j+1`.

↑ first j characters of pattern have already been matched

↑ next char matches

↑ now first j+1 characters of pattern have been matched

		0	1	2	3	4	5
`pat.charAt(j)`		A	B	A	B	A	C
	A	1		3		5	
`dfa[][j]`	B		2		4		
	C						6

⓪ — A → ① — B → ② — A → ③ — B → ④ — A → ⑤ — C → ⑥

How to build DFA from pattern?

Mismatch transition. If in state `j` and next char `c != pat.charAt(j)`, then the last `j-1` characters of input are `pat[1..j-1]`, followed by `c`.

To compute `dfa[c][j]`: Simulate `pat[1..j-1]` on DFA and take transition `c`.
Running time. Seems to require j steps.

still under construction (!)

Ex. `dfa['A'][5] = 1;`   `dfa['B'][5] = 4`

simulate BABA;
take transition 'A'
= dfa['A'][3]

simulate BABA;
take transition 'B'
= dfa['B'][3]

j	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
simulation
of BABA

How to build DFA from pattern?

Mismatch transition. If in state `j` and next char `c != pat.charAt(j)`,
then the last `j-1` characters of input are `pat[1..j-1]`, followed by `c`.

state X

To compute `dfa[c][j]`: Simulate `pat[1..j-1]` on DFA and take transition `c`.
Running time. Takes only constant time if we maintain state X.

Ex. `dfa['A'][5] = 1;`   `dfa['B'][5] = 4;`   X'= 0

from state X,
take transition 'A'
= dfa['A'][X]

from state X,
take transition 'B'
= dfa['B'][X]

from state X,
take transition 'C'
= dfa['C'][X]

0	1	2	3	4	5
A	B	A	B	A	C
Knuth-Morris-Pratt construction demo (in linear time)

Include one state for each character in pattern (plus accept state).

	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
A						
dfa[][j] B						
C						

Constructing the DFA for KMP substring search for A B A B A C

(0)   (1)   (2)   (3)   (4)   (5)   (6)

	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
A	1	1	3	1	5	1
dfa[][j] B	0	2	0	4	0	4
C	0	0	0	0	0	6

Constructing the DFA for KMP substring search for A B A B A C
Constructing the DFA for KMP substring search: Java implementation

For each state `j`:

- Copy `dfa[][X]` to `dfa[][j]` for mismatch case.
- Set `dfa[pat.charAt(j)][j]` to `j+1` for match case.
- Update `X`.

```java
public KMP(String pat)
{
    this.pat = pat;
    M = pat.length();
    dfa = new int[R][M];
    dfa[pat.charAt(0)][0] = 1;
    for (int X = 0, j = 1; j < M; j++)
    {
        for (int c = 0; c < R; c++)
            dfa[c][j] = dfa[c][X];          ← copy mismatch cases
        dfa[pat.charAt(j)][j] = j+1;        ← set match case
        X = dfa[pat.charAt(j)][X];          ← update restart state
    }
}
```

Running time. M character accesses (but space/time proportional to $R\,M$).

KMP substring search analysis

Proposition. KMP substring search accesses no more than $M + N$ chars to search for a pattern of length M in a text of length N.

Pf. Each pattern char accessed once when constructing the DFA; each text char accessed once (in the worst case) when simulating the DFA.

Proposition. KMP constructs `dfa[][]` in time and space proportional to $R\,M$.

Larger alphabets. Improved version of KMP constructs `nfa[]` in time and space proportional to M.

KMP NFA for ABABAC
Knuth-Morris-Pratt: brief history

- Independently discovered by two theoreticians and a hacker.
  - Knuth: inspired by esoteric theorem, discovered linear algorithm
  - Pratt: made running time independent of alphabet size
  - Morris: built a text editor for the CDC 6400 computer
- Theory meets practice.

...								-1
L	-1	-1	-1	-1	-1	(4)	4	4
M	-1	-1	-1	-1	-1	-1	-1	-1
N	-1	0	0	0	0	0	0	0
...								-1

Boyer-Moore skip table computation

Boyer-Moore: Java implementation

```java
public int search(String txt)
{
    int N = txt.length();
    int M = pat.length();
    int skip;
    for (int i = 0; i <= N-M; i += skip)
    {
        skip = 0;
        for (int j = M-1; j >= 0; j--)
        {
            if (pat.charAt(j) != txt.charAt(i+j))
            {
                skip = Math.max(1, j - right[txt.charAt(i+j)]);
                break;
            }
        }
        if (skip == 0) return i;
    }
    return N;
}
```
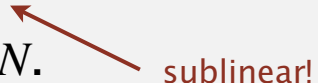

compute skip value

in case other term is nonpositive

match

Boyer-Moore: analysis

Property. Substring search with the Boyer-Moore mismatched character heuristic takes about $\sim N/M$ character compares to search for a pattern of length M in a text of length N.

sublinear!

Worst-case. Can be as bad as $\sim MN$.

```
i skip        0  1  2  3  4  5  6  7  8  9

      txt ──→ B  B  B  B  B  B  B  B  B  B

0  0          A  B  B  B  B  ←── pat
1  1             A  B  B  B  B
2  1                A  B  B  B  B
3  1                   A  B  B  B  B
4  1                      A  B  B  B  B
5  1                         A  B  B  B  B
```

Boyer-Moore variant. Can improve worst case to $\sim 3N$ character compares by adding a KMP-like rule to guard against repetitive patterns.

Rabin-Karp fingerprint search

Basic idea = modular hashing.

- Compute a hash of pattern characters 0 to $M - 1$.
- For each i, compute a hash of text characters i to $M + i - 1$.
- If pattern hash = text substring hash, check for a match.

```
            pat.charAt(i)
i      0  1  2  3  4
       2  6  5  3  5  % 997 = 613
```

```
                    txt.charAt(i)
i      0  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15
       3  1  4  1  5  9  2  6  5  3  5  8  9  7  9  3

0      3  1  4  1  5  % 997 = 508

1         1  4  1  5  9  % 997 = 201

2            4  1  5  9  2  % 997 = 715

3               1  5  9  2  6  % 997 = 971

4                  5  9  2  6  5  % 997 = 442
                                                    match
5                     9  2  6  5  3  % 997 = 929

6 ⟵ return i = 6         2  6  5  3  5  % 997 = 613
```

Efficiently computing the hash function

Modular hash function. Using the notation t_i for `txt.charAt(i)`, we wish to compute

$$x_i = t_i R^{M-1} + t_{i+1} R^{M-2} + ... + t_{i+M-1} R^0 \pmod{Q}$$

Intuition. M-digit, base-R integer, modulo Q.

Horner's method. Linear-time method to evaluate degree-M polynomial.

```
              pat.charAt()
  i    0  1  2  3  4
       2  6  5  3  5
  0    2  % 997 = 2                    R              Q
  1    2  6  % 997 = (2*10 + 6) % 997 = 26
  2    2  6  5  % 997 = (26*10 + 5) % 997 = 265
  3    2  6  5  3  % 997 = (265*10 + 3) % 997 = 659
  4    2  6  5  3  5  % 997 = (659*10 + 5) % 997 = 613
```

```java
// Compute hash for M-digit key
private long hash(String key, int M)
{
    long h = 0;
    for (int j = 0; j < M; j++)
        h = (R * h + key.charAt(j)) % Q;
    return h;
}
```

Efficiently computing the hash function

Challenge. How to efficiently compute x_{i+1} given that we know x_i.

$$x_i = t_i\, R^{M-1} + t_{i+1}\, R^{M-2} + \ldots + t_{i+M-1}\, R^0$$

$$x_{i+1} = t_{i+1}\, R^{M-1} + t_{i+2}\, R^{M-2} + \ldots + t_{i+M}\, R^0$$

Key property. Can update hash function in constant time!

$$x_{i+1} \;=\; (\, x_i \;-\; t_i\, R^{M-1}\,)\; R \;+\; t_{i+M}$$

current subtract multiply add new (can precompute R^{M-1})
value leading digit by radix trailing digit

i	...	2	3	4	5	6	7	...
current value	1	4	1	5	9	2	6	5
new value		4	1	5	9	2	6	5

→ *text*

```
      4  1  5  9  2      current value
 –    4  0  0  0  0
      1  5  9  2          subtract leading digit
            *  1  0       multiply by radix
   1  5  9  2  0
               +  6       add new trailing digit
   1  5  9  2  6          new value
```

52

Rabin-Karp substring search example

```
i    0  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15
     3  1  4  1  5  9  2  6  5  3  5  8  9  7  9  3
0    3  % 997 = 3
                                    Q
1    3  1  % 997 = (3*10 + 1) % 997 = 31
2    3  1  4  % 997 = (31*10 + 4) % 997 = 314
3    3  1  4  1  % 997 = (314*10 + 1) % 997 = 150
4    3  1  4  1  5  % 997 = (150*10 + 5) % 997 = 508   RM    R
5       1  4  1  5  9  % 997 = ((508 + 3*(997 - 30))*10 + 9) % 997 = 201
6          4  1  5  9  2  % 997 = ((201 + 1*(997 - 30))*10 + 2) % 997 = 715
7             1  5  9  2  6  % 997 = ((715 + 4*(997 - 30))*10 + 6) % 997 = 971
8                5  9  2  6  5  % 997 = ((971 + 1*(997 - 30))*10 + 5) % 997 = 442
                                                                        match
9                   9  2  6  5  3  % 997 = ((442 + 5*(997 - 30))*10 + 3) % 997 = 929
10 ← return i-M+1 = 6     2  6  5  3  5  % 997 = ((929 + 9*(997 - 30))*10 + 5) % 997 = 613
```

Rabin-Karp: Java implementation

```java
public class RabinKarp
{
   private long patHash;    // pattern hash value
   private int M;           // pattern length
   private long Q;          // modulus
   private int R;           // radix
   private long RM;         // R^(M-1) % Q

   public RabinKarp(String pat) {
      M = pat.length();
      R = 256;
      Q = longRandomPrime();

      RM = 1;
      for (int i = 1; i <= M-1; i++)
         RM = (R * RM) % Q;
      patHash = hash(pat, M);
   }

   private long hash(String key, int M)
   {  /* as before */  }

   public int search(String txt)
   {  /* see next slide */  }
}
```

a large prime
(but avoid overflow)

precompute R^{M-1} (mod Q)

Rabin-Karp: Java implementation (continued)

Monte Carlo version. Return match if hash match.

```
public int search(String txt)
{
    int N = txt.length();
    int txtHash = hash(txt, M);
    if (patHash == txtHash) return 0;
    for (int i = M; i < N; i++)
    {
        txtHash = (txtHash + Q - RM*txt.charAt(i-M) % Q) % Q;
        txtHash = (txtHash*R + txt.charAt(i)) % Q;
        if (patHash == txtHash) return i - M + 1;
    }
    return N;
}
```

check for hash collision
using rolling hash function

Las Vegas version. Check for substring match if hash match;
continue search if false collision.

Rabin-Karp analysis

Theory.   If Q is a sufficiently large random prime (about $M N^2$),
then the probability of a false collision is about $1 / N$.

Practice. Choose Q to be a large prime (but not so large to cause overflow).
Under reasonable assumptions, probability of a collision is about $1 / Q$.

Monte Carlo version.
- Always runs in linear time.
- Extremely likely to return correct answer (but not always!).

Las Vegas version.
- Always returns correct answer.
- Extremely likely to run in linear time (but worst case is $M N$).
Rabin-Karp fingerprint search

Advantages.

- Extends to 2d patterns.
- Extends to finding multiple patterns.

Disadvantages.

- Arithmetic ops slower than char compares.
- Las Vegas version requires backup.
- Poor worst-case guarantee.

Q. How would you extend Rabin-Karp to efficiently search for any one of P possible patterns in a text of length N?

Substring search cost summary

Cost of searching for an M-character pattern in an N-character text.

algorithm	version	operation count		backup in input?	correct?	extra space
		guarantee	typical			
brute force	—	MN	$1.1\,N$	*yes*	*yes*	1
Knuth-Morris-Pratt	*full DFA (Algorithm 5.6)*	$2N$	$1.1\,N$	*no*	*yes*	MR
	mismatch transitions only	$3N$	$1.1\,N$	*no*	*yes*	M
Boyer-Moore	*full algorithm*	$3N$	N/M	*yes*	*yes*	R
	mismatched char heuristic only (Algorithm 5.7)	MN	N/M	*yes*	*yes*	R
Rabin-Karp[†]	*Monte Carlo (Algorithm 5.8)*	$7N$	$7N$	*no*	*yes*[†]	1
	Las Vegas	$7N$[†]	$7N$	*yes*	*yes*	1

† probabilisitic guarantee, with uniform hash function
